Computer Lab 2 Computational Statistics

Linköpings Universitet, IDA, Statistik

2019/01/25

Kurskod och namn: 732A90 Computational Statistics

Datum: 2019/01/24—2019/02/07 (lab session 25 January 2019)

Delmomentsansvarig: Krzysztof Bartoszek and Eric Herwin

Instruktioner: This computer laboratory is part of the examination for the

Computational Statistics course

Create a group report, (that is directly presentable, if you are a presenting group),

on the solutions to the lab as a .PDF file.

Be concise and do not include unnecessary printouts and figures produced by the software and not required in the assignments.

All R code should be included as an appendix into your report.

A typical lab report should 2-4 pages of text plus some amount of

figures plus appendix with codes.

In the report reference ALL consulted sources and disclose ALL collaborations.

The report should be handed in via LISAM

(or alternatively in case of problems e-mailed to krzysztof.bartoszek@liu.se

or Eric Herwin erihe068@student.liu.se or Sara Johansson sarjo775@student.liu.se),

by **23:59 7 February 2019** at latest.

Notice there is a final deadline of 23:59 1 April 2019 after which no submissions nor corrections will be considered and you will have to

redo the missing labs next year.

The seminar for this lab will take place 7 March 2019.

The report has to be written in English.

Question 1: Optimizing a model parameter

The file mortality_rate.csv contains information about mortality rates of the fruit flies during a certain period.

1. Import this file to R and add one more variable LMR to the data which is the natural logarithm of Rate. Afterwards, divide the data into training and test sets by using the following code:

```
n=dim(data)[1]
set . seed (123456)
id=sample(1:n, floor(n*0.5))
train=data[id,]
test=data[-id,]
```

2. Write your own function myMSE() that for given parameters λ and list pars containing vectors X, Y, Xtest, Ytest fits a LOESS model with response Y and predictor X using loess() function with penalty λ (parameter enp.target in loess()) and then predicts the model for Xtest. The function should compute the predictive MSE, print it and return as a result. The predictive MSE is the mean square error of the prediction on the testing data. It is defined by the following Equation (for you to implement):

$$\text{predictive MSE} = \frac{1}{\texttt{length(test)}} \sum_{i \text{th element in test set}} \left(\texttt{Ytest[i]} - \texttt{fYpred(X[i])} \right)^2,$$

where fYpred(X[i]) is the predicted value of Y if X is X[i]. Read on R's functions for prediction so that you do not have to implement it yourself.

- 3. Use a simple approach: use function myMSE(), training and test sets with response LMR and predictor Day and the following λ values to estimate the predictive MSE values: $\lambda = 0.1, 0.2, \ldots, 40$
- 4. Create a plot of the MSE values versus λ and comment on which λ value is optimal. How many evaluations of myMSE() were required (read ?optimize) to find this value?
- 5. Use optimize() function for the same purpose, specify range for search [0.1, 40] and the accuracy 0.01. Have the function managed to find the optimal MSE value? How many myMSE() function evaluations were required? Compare to step 4.
- 6. Use optim() function and BFGS method with starting point $\lambda = 35$ to find the optimal λ value. How many myMSE() function evaluations were required (read ?optim)? Compare the results you obtained with the results from step 5 and make conclusions.

Question 2: Maximizing likelihood

The file data.RData contains a sample from normal distribution with some parameters μ , σ . For this question read ?optim in detail.

- 1. Load the data to R environment.
- 2. Write down the log-likelihood function for 100 observations and derive maximum likelihood estimators for μ , σ analytically by setting partial derivatives to zero. Use the derived formulae to obtain parameter estimates for the loaded data.
- 3. Optimize the minus log-likelihood function with initial parameters $\mu = 0$, $\sigma = 1$. Try both Conjugate Gradient method (described in the presentation handout) and BFGS (discussed in the lecture) algorithm with gradient specified and without. Why it is a bad idea to maximize likelihood rather than maximizing log-likelihood?
- 4. Did the algorithms converge in all cases? What were the optimal values of parameters and how many function and gradient evaluations were required for algorithms to converge? Which settings would you recommend?
